

A link between measures of Gross National Product, and measures of corruption

Abstract

This paper establishes a link between a countries economic performance as measured by Gross National Product (GNP) and a compound measure of Transparency, Corruption Perceptions Index (CPI), and (TI 2002).

CPI is a measurement that should provide an indication as to a countries reputation in the eyes of investors and traders for openness and information disclosure in government and non governmental organisations, in relation to corruption, bribery and extra non-justifiable payments.

Corruption involves the behaviour of public officials either elected or appointed, by which they unlawfully enrich themselves or those close to them. This is probably the case of the disparate performance of developing countries, where some are experiencing economic growth while others are falling behind. (Helman 2000).

There has been comment in the press about the relationship between corrupt practices, and a countries economic performance. (Anon 2001), (Lobe 2001) and (Perlez 2002).

This evidence is presented as a countries ability to attract trade and investment, which should be possible to measure by examining it's economic performance.

This paper does not attempt to analyse the accuracy of this evidence, it instead shows an empirical link between measures of GNP and CPI, which along with the anecdotal evidence support the view that a countries economic performance is indeed tied to it's reputation for corruption and transparency.

Introduction

This paper collects data from the World Bank and Transparency International into a form that can be analysed easily by suitable well understood statistical methods such as Ordinary Least Squares (OLS). These are then presented as a set of tables and figures which show a distinct link between measures of GDP as defined by the World Development Bank (World Development Bank 2002 a, c) divided by measures of population. (World Development Bank 2002 b).

Data and Methodology

The data used in this paper is presented in full as a Table 1 presented in the appendix along with the resultant OLS graphs Figures 1 and 2. ANOVA, correlation and regression statistics are presented in tables 2 and 3) (Walpole et al 1998, Chapter 11)

The provides definitions of the measures of GDP Gross Domestic Product and GDP (PPP) Gross Domestic Product adjusted for Purchasing Power Parity are available from the internet, and from the references (op cit). The definition of CPI is

"CPI 2002 Score relates to perceptions of the degree of corruption as seen by business people and risk analysts, and ranges between 10 (highly clean) and 0 (highly corrupt)"

It is derived from a series of survey sources that have a variety of questions relating to corruption, bribery and transparency within the countries listed. A country is only listed if there are a set of survey's, and there is longitudinal data over several years. (TPI 2002).

There are some gaps in the World Bank Data, where the World Bank has had to interperate the figures of certain countries. These are identified in Table 1 along with the interpretation used by the World Bank.

A date of September 2002 was chosen as the base calendar date, where all figures used were adjusted to that date, or as near to it in that calendar year. The data is as complete as possible using the given sources. The data provided is enough to give a good indication as to the applicabiity of comparing CPI against measures of economic performance. Some 101 economies (countries) are available in the TPI report, and these are compared against the same economies data from the World Bank

Table 1 is therefore a combination of the Transparency Internationals report, countries 101 in total, and comparative figures from the World Bank. The Table is placed in order of CPI, so as to test the regression on this measure of corruption. Colume 1 and 2 are the economies (countries) and the CPI score respectively

The raw GDP in column 3 in Millions of US dollars alongside the population in millions. From which the GDP per Capita is calculated (column 4). Another measure of GDP was also available from the same source which measures Purchasing Power Parity. (PPP), and is in column 6. This divided by Population gives GDP(PPP)/ Capita in column 7.

The data was then subjected to OLS analysis, and the reults of GDP/Capita and GDP(PPP) / Capita are shown in tables 2 and 3 respectively. The graphs of the analysis are agin shown in the appendix as figures 1 and 2 respectively.

Results

Figure 1 shows the calculated GDP/Capita plotted against CPI as defined above. Although there is a general scattering of points around the 'best fit'line there is a degree of correlation as determined and shown in table 2, in the appendix
The R Squared value of 0.72 (rounded to two decimal places) is indicative of a good correlation between CPI index and GDP per capita, the ANOVA statistics provide a predicted straight line, which is shown in figure 1 for comparison purposes.

Figure 1

Regression line (Predicted Y), GDP / Capita (Y) against CPI Index

Similarly Figure 2 shows GDP(PPP) per Capita against CPI. Again the figure for R Squared of 0.78 (adjusted to two decimal places) is a good indication of correlation between CPI and GDP(PPP) per Capita. The full ANOVA statistics are shown in Table 3 in the appendix. Figure 2 also shows the predicted line for comparison.

Figure 2

Regression line (Predicted Y), GDP(PPP) / Capita (Y) against CPI Index

In both cases there is a good correlation between the measures of both types of GDP and the CPI index. In percentage terms 72% and 78% respectively of GDP / Capita and GDP(PPP) / Capita can be explained by a linear relationship.

The economies at the lower end of the CPI index, and low GDP per Capita and GDP (PPP) per Capita have an international reputation for corruption, mis management and lack of transparency (Lobe op cit)

Also they display in action or an in ability to tackle multiple economic problems associated with corruption bribery and lack of transparency (Arif 2002).

They also display difficulty in increasing GDP by percentages that are normally associated with developing countries and are subject to major economic and non economic shocks (Dhume 2002)

Similar evidence suggests that there is a decrease in external investment and multinationals moving to a more open and transparent regime (Shari 2002).

These individual examples of economies are backed by the summary comments of Peter Eigen given at the release of the TPI report for 2002 (TPI op cit).

"Political elites and their cronies continue to take kickbacks at every opportunity. Hand in glove with corrupt business people, they are trapping whole nations in poverty and hampering sustainable development. Corruption is perceived to be dangerously high in poor parts of the world, but also in many countries whose firms invest in developing nations."

There has been some empirical research undertaken recently to examine the consequences and causes of corruption, which includes the effects on GDP.

The difficulty is that the studies indicate that it is difficult to identify any causality from the examination of a spectrum of variables and corruption directly.(Lambsdorff, 1999) However, there has been fruitful work on the relationship between GDP per head and corruption. This paper extends this earlier work to examine GDP per Capita (head) and GDP (PPP) per Capita against a collective measure of corruption (CPI). It shows that

there is a correlation. (Marginally stronger in the case of GDP(PPP) per Capita.) without the resort to dummy variables as reported in Lambsdorff. (Lambsdorf op Cit.).

Also the data used in this paper extends the number of economies (countries) studied to nearer 100. This improves the significance of the regression, and the correlation by comparison with other results using similar cross country data.

Conclusion

The CPI index is a useful indicator of economic performance of an individual country. However, it cannot be used exclusively of its own, as many countries have similar scores. If the CPI index is used in addition to another measure of Economic performance such as GDP per Capita and GDP (PPP) per Capita then it can illustrate along with other evidence the individual countries economic performance against others.

As a performance indicator CPI is useful for assessing the general likelihood of performance, and hence the 'attractiveness' of a particular economy or otherwise for trade and investment.

Therefore it is recommended as an empirical measure for the assessment of performance, coupled with additional measures such as GDP per Capita and GDP (PPP) per Capita.

Further work suggests itself from this analysis of CPI and GDP. The relationships between trading and economic blocks such as the European Union and Organisation for Economic Development (OECD), South East Asia could be considered if suitable data were available.

The data needs to be examined for multivarience if any, and possible other measures of economic performance such as ability to attract investment.
